

# How to Use OV7670 Camera Module with Arduino

Cameras have always dominated the electronics industry as it has lots of applications such as visitor monitoring system, surveillance system, attendance system etc. Cameras that we use today are smart and have a lot of features that were not present in earlier cameras. While todays digital cameras not only capture images but also captures high-level descriptions of the scene and analyse what they see. It is used extensively in Robotics, Artificial Intelligence, Machine Learning etc. The Captured frames are processed using Artificial Intelligence and Machine Learning, and then used in many applications like Number plate detection, object detection, motion detection, facial recognition etc.

In this tutorial we will interface most widely used **camera module OV7670 with Arduino UNO**. The camera module OV7670 can be interfaced with **Arduino Mega** with same pin configuration, code and steps. The camera module is hard to interface because it has large number of pins and jumbled wiring to carry out. Also the wire becomes very important when using camera modules as the choice of the wire and length of the wire can significantly affect the picture quality and can bring noise.

We have already done ample projects on Cameras with different kind of Microcontrollers and IoT Devices such as:

- [Visitor Monitoring System with Raspberry Pi and Pi Camera](#)
- [IOT based Raspberry Pi Home Security System with Email Alert](#)
- [Raspberry Pi Surveillance Camera with Motion Capture](#)

The **Camera OV7670** works on 3.3V, so it becomes very important to avoid Arduino which gives 5V output at their Output GPIO pins. The OV7670 is a FIFO camera. But in this tutorial, the picture or frames will be grabbed without FIFO. This tutorial will have simple steps and simplified programming **to interface OV7670 with Arduino UNO**.

## Components Required

- Arduino UNO

- OV7670 Camera Module
- Resistors(10k, 4.7k)
- Jumpers

**Software Required:**

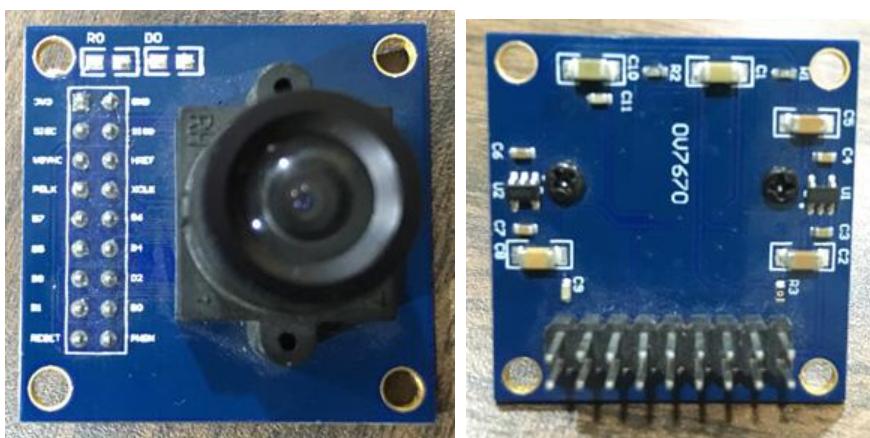

- Arduino IDE
- [Serial Port Reader](#) (To analyze Output Image)

## Things to Remember about Camera Module OV7670

OV7670 Camera Module is a FIFO camera Module available from different Manufacturers with different pin Configurations. The OV7670 provides full frame, windowed 8-bit images in a wide range of formats. The image array is capable of operating at up to 30 frames per second (fps) in VGA. The OV7670 includes

- Image Sensor Array(of about 656 x 488 pixels)
- Timing Generator
- Analog Signal Processor
- A/D Converters
- Test Pattern Generator
- Digital Signal Processor(DSP)
- Image Scaler
- Digital Video Port
- LED and Strobe Flash Control Output

The OV7670 image sensor is controlled using Serial Camera Control Bus (SCCB) which is an [I2C interface](#) (SIOC, SIOD) with a maximum clock frequency of 400KHz.

The Camera comes with handshaking signals such as:

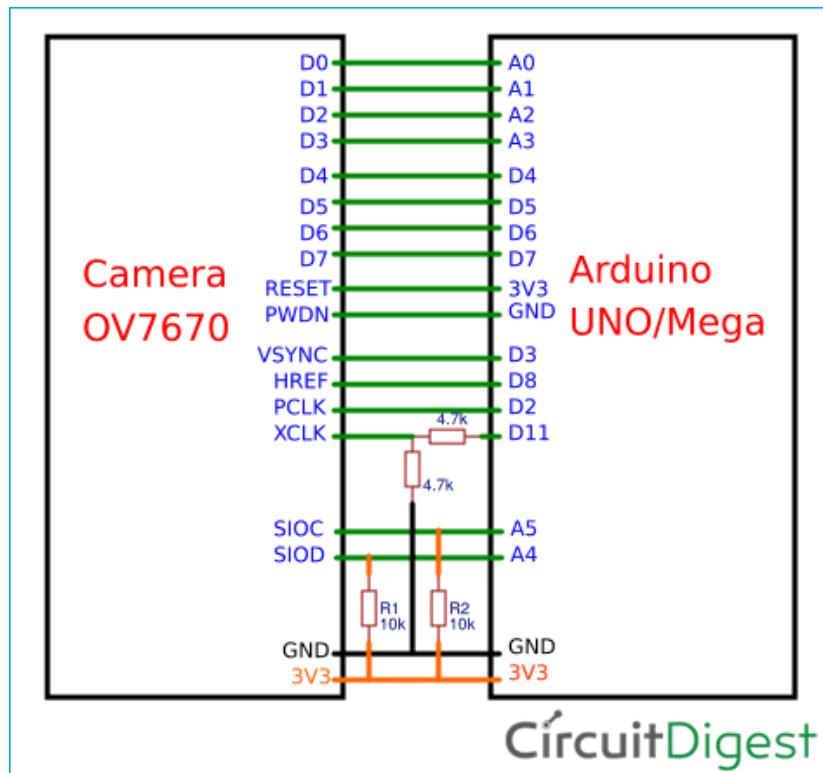

- **VSYNC:** Vertical Sync Output – Low during frame
- **HREF:** Horizontal Reference – High during active pixels of row
- **PCLK:** Pixel Clock Output – Free running clock. Data is valid on rising edge

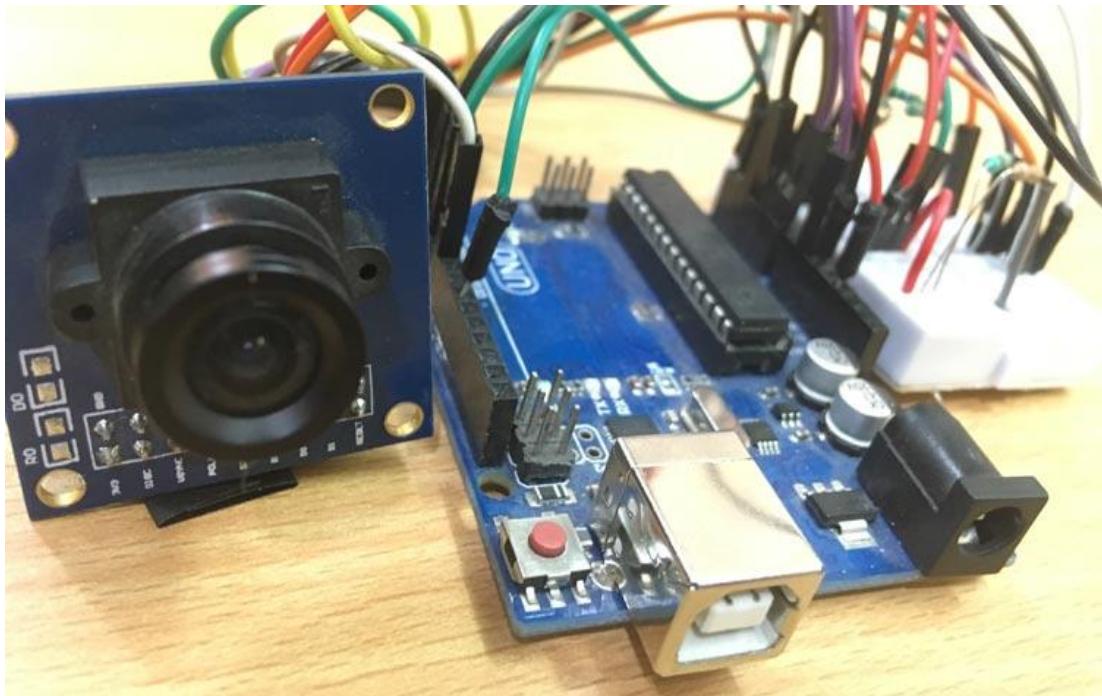

In addition to this, it has several more signals such as

- **D0-D7:** 8-bit YUV/RGB Video Component Digital Output
- **PWDN:** Power Down Mode Selection – Normal Mode and Power Down Mode
- **XCLK:** System Clock Input
- **Reset:** Reset Signal

The OV7670 is clocked from a 24MHz oscillator. This gives a Pixel Clock(PCLK) output of 24MHz. The FIFO provides 3Mbps of video frame buffer memory. The test pattern generator features 8-bar color bar pattern, fade-to-gray color bar patter. Now let's start programming the Arduino UNO for testing Camera OV7670 and grabbing frames using serial port reader.

## Circuit Diagram

## Programming Arduino UNO

The programming starts with **including required library necessary for OV7670**. Since OV7670 runs on I2C interface, it includes `<util/twi.h>` library. The libraries used in this project are built-in libraries of ArduinolIDE. We just have to include the libraries to get the job done.

After this, the registers need to be modified for OV7670. The program is divided into small functions for better understanding.

The `Setup()` comprises all the initial setups required for only image capturing. The first function `isarduinoUnoInut()` which is used to initialise the arduino uno. Initially it disables all the global interrupts and sets the communication interface configurations such as the PWM clock, selection of interrupt pins, presclaer selection, adding parity and stop bits.

```
arduinoUnoInut();
```

After configuring the Arduino, the camera has to be configured. To initialise the camera, we only have the options to change the register values. The register values need to be changed from the default to the custom. Also add required delay depending upon the

microcontroller frequency we are using. As, slow microcontrollers have less processing time adding more delay between capturing frames.

```
void camInit(void){  
  
    writeReg(0x12, 0x80);  
  
    _delay_ms(100);  
  
    wrSensorRegs8_8(ov7670_default_regs);  
  
    writeReg(REG_COM10, 32); //PCLK does not toggle on HBLANK.  
  
}
```

The camera is set to take a QVGA image so the resolution need to be selected. The function configures the register to take a QVGA image.

```
setResolution();
```

In this tutorial, the images are taken in monochrome, so the register value is set to output a monochrome image. The function sets the register values from register list which is predefined in the program.

```
setColor();
```

The below function is write to register function **which writes the hex value to register**. If you get the scrambled images then try to change the second term i.e. 10 to 9/11/12. But most of the time this value works fine so no need to change it.

```
writeReg(0x11, 10);
```

This function is used to get the image resolution size. In this project we are taking pictures in the size of 320 x 240 pixels.

```
captureImg(320, 240);
```

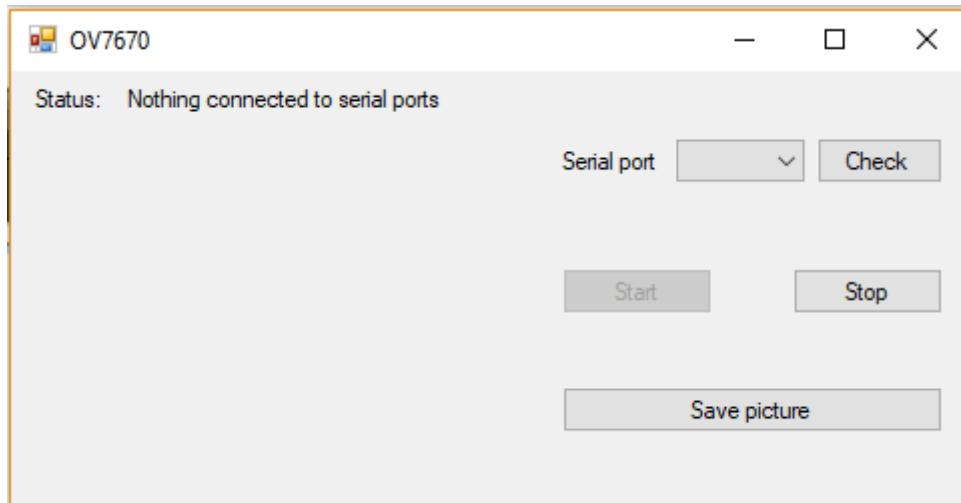

Other than this, the code also has the I2C configurations divided in to several parts. Just to get the data from camera, the I2C configurations has Start, Read, Write, Set Address function which are important when using [I2C protocol](#).

You can find the **complete code with a demonstration video** at the end of this tutorial. Just Upload the code and open the Serial Port Reader and grab the frames.

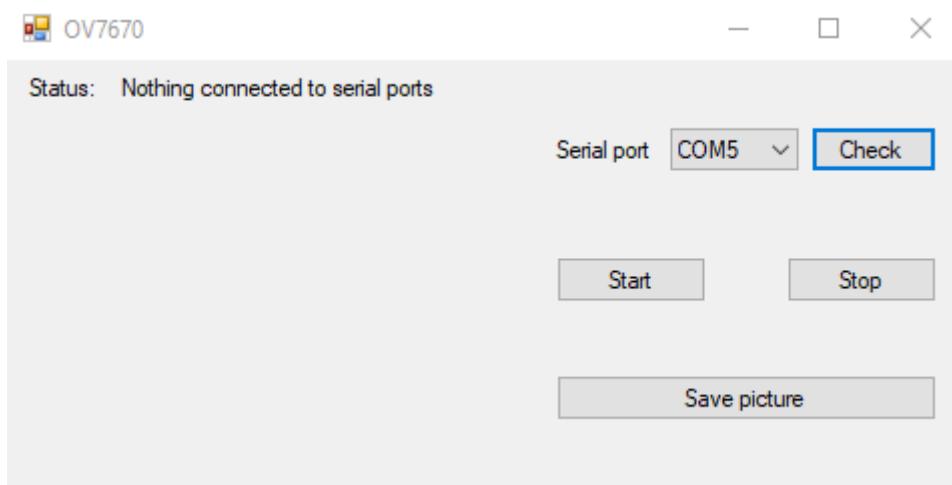

## How to Use Serial Port Reader for reading Images

Serial Port Reader is a simple GUI, [download it from here](#). This captures the base64 encode and decodes it to form an image. Just follow these simple steps to use Serial Port Reader

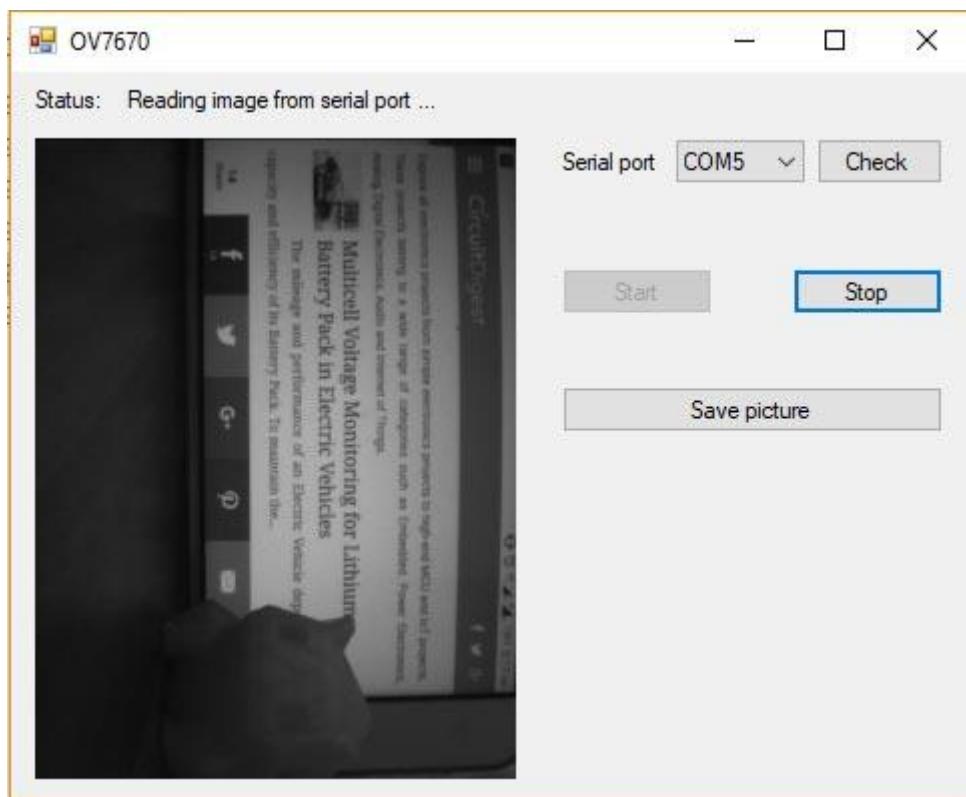

**Step 1:** Connect Your Arduino to any USB Port of your PC

**Step 2:** Click on “Check” to find your Arduino COM Port

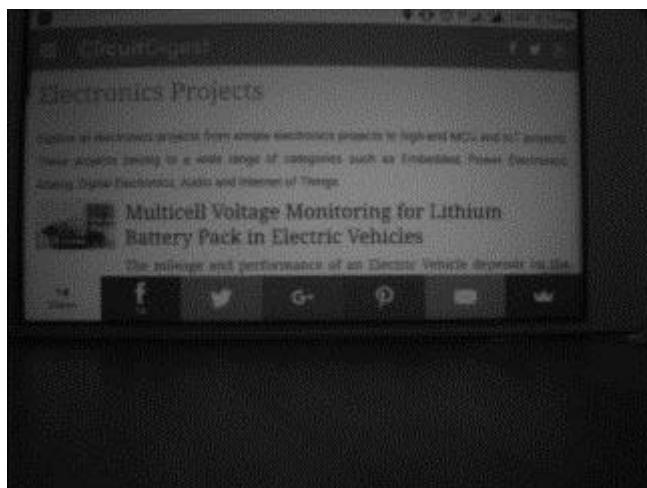

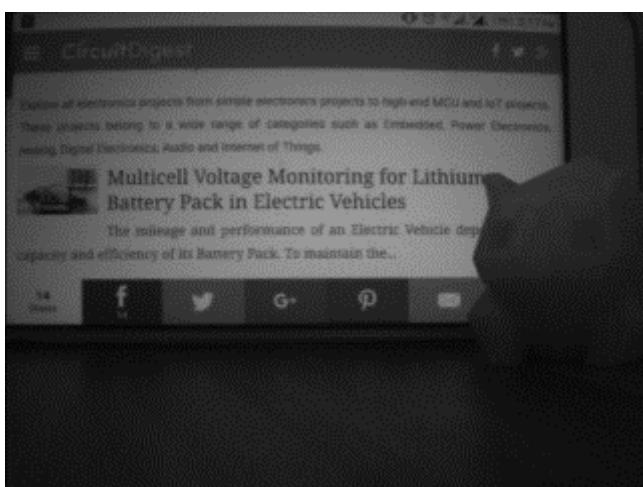

**Step 3:** Finally click on “Start” button to start reading serially.

**Step 4:** One can also save this pictures by just clicking on “Save Picture”.

Below are Sample Images Taken from the OV7670

## Precautions when using OV7670

- Try to use wires or jumpers as short as possible
- Avoid any loose contact to any pins on Arduino or OV7670
- Be careful about connecting as large number of wiring can lead short circuit
- If the UNO gives 5V output to GPIO then use Level Shifter.
- Use 3.3V Input for OV7670 as exceeding voltage than this can damage the OV7670 module.

This project is created to give overview of using a camera module with Arduino. Since Arduino has less memory, so the processing may not be as expected. You can use different controllers which has more memory for processing.

## Code
